ABSTRACT: Field theory in the presence of extra dimensions has offered interesting solutions to the gauge hierarchy problem, and inspired many attempts to understand the fermion mass generation mechanism. We study the behaviour of a bulk fermion field subject to non-standard boundary conditions under Z_2 symmetry in a slice of AdS_5 . These *pseudo-Majorana* boundary conditions relate the 5d spinor fields to their 5d charge conjugate and generate Majorana spinors in four-dimensions. There is a zero mode localized on the visible brane and the masses of Kaluza-Klein excitations are naturally of order the weak-scale. We make connection to neutrino phenomenology. We also demonstrate that, contrary to previous claims, a bulk singlet scalar field cannot provide a successful mechanism to generate a suppressed Majorana mass for Standard Model neutrinos localized on the visible brane.

KEYWORDS: Physics beyond the Standard Model, Neutrino physics, Extra dimensions, Majorana spinors.

1. Introduction

Theories with extra spatial dimensions have received great attention during the past decade, offering plausible solutions to the gauge hierarchy problem [1], and inspiring many attempts to understand the fermion mass generation mechanism.

Large flat extra dimensions [2] can provide a suppression mechanism of fermion masses via a reduction of Yukawa couplings by a volume factor $1/\sqrt{V}$, where V is the volume of the compact extra dimensional space [2]. Many attempts have been considered in this context to generate small masses for the Standard Model neutrinos, see e.g. [3, 4, 5].

Interesting alternatives arise when a non-factorizable geometry is considered [1, 6, 7]. In this case the background metric entangles the four dimensional space to the extra dimensions via “warp” factors $\sim e^{-k|y|}$ induced by the (constant) curvature k of the extra spatial dimensions y . The role of the volume of large flat extra dimensions is now played by the warp factor, without implying stringent constraints on the size of the extra dimension. A particularly successful construction has been proposed in [1] where an AdS_5 space has been considered with the fifth dimension y circularly compactified on a radius R and orbifolded to S^1/Z_2 . The orbifold fixed points $y = 0$ and $y = \pi R$ can be identified with 3-branes with positive and negative tension: the Planck (or invisible) brane at $y = 0$ and the TeV (or visible) brane at $y = \pi R$. Any fundamental mass parameter m_0 in the original theory will be converted to an effective mass parameter $m \sim m_0 e^{-k\pi R}$ on the visible brane, via the warping action of the slice of AdS_5 between the two branes. For $kR \sim 11$ all masses of particles confined to the visible brane are naturally of order the weak scale.

One of the long standing questions in particle physics remains the one of finding a mechanism that naturally explains the apparent hierarchy of fermion masses in the Standard Model and why neutrino masses are much smaller than all charged lepton masses. The addition of extra dimensions offers many new possibilities, along with new challenges: the suppression of additional operators might become a far more complicated task in an extra dimensional framework. Any plausible mechanism of generation of observed phenomena, must also guarantee a suppression of processes like proton decay, flavour changing neutral currents and lepton flavour violation.

Many interesting attempts have been made along the years in order to explain the smallness of neutrino masses with mechanisms induced by the presence of extra dimensions. This has been done by adding fermion fields to the bulk and maintaining their Dirac nature [8], or by adding a Majorana mass term [9] or considering higher dimensional Majorana couplings [10], or adding extra scalar fields to induce a small Majorana mass on the visible brane [11]. The dynamics of bulk fermion, scalar and vector fields has been extensively considered in a supersymmetric context in e.g. [12, 13].

In this paper we consider a particular mechanism to generate a Majorana spinor on the visible brane by imposing a Z_2 transformation property of the bulk fermion fields which mixes the fields and their charge conjugates, analogously to the Majorana condition in four dimensions. This boundary condition is tailored for neutrinos, and it is the generalization to a warped geometry of the boundary conditions first proposed in [14] in the case of flat extra dimensions. We show how these *pseudo-Majorana* boundary conditions far more

constrain the Kaluza-Klein spectrum with respect to the ordinary Z_2 boundary conditions when reducing from five to four dimensions.

The paper is organized as follows. In Section 2 we describe the framework, impose the *pseudo-Majorana* boundary conditions and derive the Kaluza-Klein spectrum of the theory. Here we build the connection between the 5D and the 4D charge conjugation operators and we show that the boundary conditions generate one Majorana spinor with peculiar properties induced by the warped geometry. In Section 3 we attempt some more phenomenological considerations, identifying the bulk Majorana spinor with a sterile neutrino or with a Majorana Standard Model neutrino. In Section 4 we summarize alternative attempts to generate small Majorana masses and we reconsider the derivation of ref. [11]. Our conclusions are in Section 5.

2. Bulk fermions with pseudo-Majorana boundary conditions

We consider a scenario with one extra dimension as first introduced in ref. [1]. The fifth dimension y is circularly compactified on a radius R and orbifolded to S^1/Z_2 on the interval $-\pi R \leq y \leq \pi R$. The background metric is non-factorizable and describing a slice of AdS_5 . The orbifold fixed points are $y = 0$ and πR which can be naturally interpreted as the location of two 3-branes, where the stress-energy tensor solution of the Einstein's equation is non zero. The Planck scale brane is located at $y = 0$ and the TeV or visible brane is located at $y = \pi R$. This thin-brane case can also be understood as the limiting behaviour of a thick domain-wall solution.

The action for a spin-1/2 Dirac fermion ψ living in the bulk is the Dirac action generalized to curved five-dimensional space with constant curvature and can be written as follows

$$S = \int d^4x \int dy \sqrt{-g} \left(i\bar{\psi} g^{MN} \gamma_M D_M \psi - m\bar{\psi}\psi \right), \quad (2.1)$$

where $g = \det(g_{MN}) = -e^{-8\sigma}$ is the determinant of the metric tensor with $\sigma = k|y|$ and k the constant curvature along the fifth dimension. We use capital indices $M, N \dots$ for objects defined in curved space and lower-case greek indices $\mu, \nu, \dots \alpha, \beta$ for objects defined in the tangent frame: in our notation $\mu = 0, 1, 2, 3$ and $M = (\mu, 5)$.

A line-element solution of the Einstein's equations in five-dimensions, which respects four-dimensional Poincare invariance, is given by [1]

$$ds^2 = e^{-2\sigma} \eta_{\mu\nu} dx^\mu dx^\nu + dy^2, \quad (2.2)$$

with flat metric tensor $\eta_{\mu\nu} = (-1, 1, 1, 1)$ and $\mu, \nu = 0, 1, 2, 3$. The warp factor $e^{-2\sigma}$ entangles the four dimensional space-time to the fifth dimension y rendering the geometry non-factorizable. This is a special case of an AdS_5 geometry. This solution can only be trusted if $k < M$, i.e. the bulk curvature is small compared with the fundamental Planck scale. The gamma matrices γ^M are the curved space Dirac matrices, $\gamma^M = (\gamma^\mu, \gamma_5)^1$. They are related to the flat space ones through the *vielbein* e_α^M , $\gamma^M = e_\alpha^M \gamma^\alpha$ with $e_\alpha^M = (e^\sigma, e^\sigma, e^\sigma, e^\sigma, 1)$.

¹We use the Dirac representation of the gamma matrices unless differently stated

We have introduced the covariant derivative acting on the fermion field in curved space $D_M = \partial_M + \Gamma_M$, where Γ_M is the spin connection²

$$\Gamma_\mu = \frac{1}{2}\gamma_5\gamma_\mu\frac{d\sigma}{dy} \quad \Gamma_5 = 0. \quad (2.3)$$

For the sake of simplicity, we do not consider a bulk gauge field coupled to the bulk fermion in this paper. An investigation of this case for flat extra dimensions can be found in ref. [14]. We have introduced a bulk mass term with mass m for the fermion field. The mass m can be typically generated by scalar fields acquiring a vacuum expectation value in the higher dimensional theory. It is in general complex valued $m = |m|e^{i\alpha}$, however its phase is irrelevant at this level, since we can always rotate the Weyl spinors by a phase which cancels the phase in the mass term and leaves the action invariant. Hence, we can set $m = |m|$ without loss of generality.

The invariance of the bulk mass term under the Z_2 parity transformation $y \rightarrow -y$ can be guaranteed in two ways: the mass m and the scalar fermion bilinear $\bar{\psi}\psi$ are both odd or both even under a Z_2 -parity transformation. A Z_2 odd mass parameter can be explained as the vev of a scalar field with an odd “kink” profile. The vacuum configuration of the scalar field resembles in this case the background 3-form field in the dimensional reduction of the Horava-Witten theory [15]. The Z_2 -even case appears when pseudo-Majorana boundary conditions are imposed, as it will be discussed in the following.

The odd case

A Z_2 odd mass parameter is required when ordinary boundary conditions for the bulk fermion fields are imposed. These have been extensively considered in the literature [8, 12]. The bulk Dirac field transforms under Z_2 as

$$\psi(x, -y) = \pm\gamma_5\psi(x, y), \quad (2.4)$$

where the sign can only be determined by the fermion interactions. This transformation property implies that the fermion scalar bilinear $\bar{\psi}\psi$ is odd under Z_2 , $\bar{\psi}(-y)\psi(-y) = -\bar{\psi}(y)\psi(y)$. The invariance of the action under Z_2 thus requires a Z_2 odd mass of the type $m(y) = m\epsilon(y)$ with $\epsilon(y)$ the sign function. Given that the left- and right-handed components of the Dirac field satisfy $\psi_{L,R} = \mp\gamma_5\psi_{L,R}$, ordinary boundary conditions will imply that the L-handed field is Z_2 -odd and the R-handed field even, or viceversa. The odd component will vanish at the fixed points of the orbifolding $y = 0$ and $y = \pi R$ - where πR is identified with $-\pi R$ ³.

The odd bulk mass term vanishes at the boundaries $y = 0, \pm\pi R$. Thus we conclude that the most general mass term allowed by ordinary boundary conditions contains a bulk contribution and no boundary terms.

²This is in agreement with ref. [12] and one can easily check this to be equivalent to the prescription derived in ref. [8].

³The orbifolding condition that identifies fields at $y = \pi R$ and $y = -\pi R$ is equivalent to periodic boundary conditions imposed on universal flat dimensions of size L , i.e. $\psi(y) = \psi(y + L)$.

The even case

The Z_2 -even case has instead an even mass parameter m and an even fermion bilinear which does not vanish at the orbifold fixed points, so that both a bulk mass contribution and a boundary contribution are in general allowed. We consider an especially suitable type of unordinary boundary conditions, first introduced in ref. [14] in the context of universal flat extra dimensions. We call them *pseudo-Majorana* boundary conditions, since they relate the bulk fermion field to its charge-conjugate field in the five-dimensional theory and they are able to generate the Majorana condition $\psi = \psi^c$ back into four dimensions.

The pseudo-Majorana boundary conditions are imposed on the Dirac fields living in the 5D bulk as follows

$$\psi(x, -y) = e^{-i\delta} \gamma_5 \psi^c(x, y), \quad (2.5)$$

where a phase factor is allowed in the most general case, and $\psi^c = C (\bar{\psi})^T$ is the charge conjugate field with $C (\equiv C_5)$ the charge conjugation matrix of the five dimensional theory. At this point we only need to know the following properties of C :

$$C^\dagger = C^T = C^{-1} = -C \quad C \Gamma_a C^{-1} = \Gamma_a^T, \quad \Gamma_a = (\gamma_\mu, \gamma_5), \quad (2.6)$$

while in section (2.4) we shall state the relation between the 5D charge conjugation operator and the charge conjugation operator in four dimensions. A valid matrix representation of the 5D charge conjugation operator in Dirac or Weyl basis is $C = \gamma_1 \gamma_3$. It is clear that any boundary condition which induces a mixing of a fermion field and its charge conjugate will only be allowed for electrically-neutral fields, and this is the case of neutrinos. Any additional $U(1)$ symmetry, under which the fermion is charged, will be broken by the boundary conditions in eq. (2.5).

In order to make connection to the charge conjugate field, notice that the action in eq. (2.1) can equivalently be written in terms of the field ψ and its charge conjugate in a compact form, also extensively used in ref. [14]

$$S = \int d^4x \int dy \sqrt{-g} \left(i \bar{\Psi} g^{MN} \gamma_M D_N \Psi - \bar{\Psi} \mathcal{M} \Psi \right), \quad (2.7)$$

where we have defined the following vector of fields and mass matrix

$$\Psi = \begin{pmatrix} \psi^c \\ \psi \end{pmatrix} \quad \mathcal{M} = \begin{pmatrix} -m & 0 \\ 0 & m \end{pmatrix}. \quad (2.8)$$

To derive eq. (2.7) one observes that the action of the 5D charge conjugation operator implies $(\psi^c)^c = -\psi$, hence $\bar{\psi} \psi = -\bar{\psi}^c \psi^c$ and $\bar{\psi} \gamma^M D_M \psi = \bar{\psi}^c \gamma^M D_M \psi^c$. These identities lead straightforwardly to the form of eq. (2.7). The pseudo-Majorana boundary condition on the vector of fields Ψ reads as follows

$$\Psi(x, -y) = \sigma_1 e^{-i\sigma_3 \delta} \gamma_5 \Psi(x, y) = -\sigma_3 e^{i\sigma_3 \delta} \gamma_5 \Psi^c(x, y). \quad (2.9)$$

The vector of fields $\Psi(x, y)$ is also subject to periodic boundary conditions, so that $\Psi(x, \pi R) = \Psi(x, -\pi R)$. This is a very natural condition to impose. However, this type of constraint can also be generalized, see for example [14].

We perform a Kaluza-Klein decomposition of the 5D fields in order to be able to derive an action for fermions in four-dimensions. We have the choice of working in terms of the fields ψ and ψ^c , or in terms of L- and R-handed fields $\psi_{L,R}$, or in terms of the vector of fields Ψ . We choose to decompose the 5D fields in terms of L- and R-handed components to keep our derivation easily comparable with the Dirac case of ordinary boundary conditions extensively analyzed in the literature [8, 12]. We write

$$\psi_{L,R}(x, y) = \frac{1}{\sqrt{2\pi R}} \sum_{n=0}^{\infty} \psi_{n,L,R}(x) e^{2\sigma} \hat{f}_{n,L,R}(y), \quad (2.10)$$

where in the most general case the y -dependent functions $\hat{f}_{n,L,R}(y)$ are complex valued, and subject to the specific boundary conditions. The same decomposition for the charge conjugate field $\psi^c(x, y) = C\bar{\psi}^T(x, y) = C\gamma_0\psi^*(x, y)$ reads

$$(\psi_{L,R})^c(x, y) = \frac{1}{\sqrt{2\pi R}} \sum_{n=0}^{\infty} (\psi_{n,L,R})^c(x) e^{2\sigma} \hat{f}_{n,L,R}^*(y) \quad (2.11)$$

and the identity $(\psi^c)_{L,R} = (\psi_{R,L})^c$ holds under the action of the 5D charge conjugation operator.

2.1 Imposing Pseudo-Majorana boundary conditions

The boundary conditions in eq. (2.5) constrain the functions $\hat{f}_{n,L,R}(y)$ through the Kaluza-Klein decomposition of eqs. (2.10) and (2.11), so that one only independent function remains, associated to one 4D Weyl spinor analogously to what happens when imposing the Majorana condition in four dimensions. Writing eq. (2.5) in terms of L- and R-handed fields we obtain

$$\begin{aligned} e^{i\delta}\psi_L(x, -y) &= -(\psi^c)_L(x, y) = -(\psi_R)^c(x, y) \\ e^{i\delta}\psi_R(x, -y) &= +(\psi^c)_R(x, y) = +(\psi_L)^c(x, y). \end{aligned} \quad (2.12)$$

When deriving the boundary conditions on the KK fields we have the choice to absorb the phase factor $e^{i\delta}$ into a) the constraints on the 4D fields $\psi_n(x)$ or into b) the constraints on the y -dependent functions $\hat{f}_n(y)$. Clearly, both choices are equivalent. In the first case one has

$$\psi_n(x) = e^{-i\delta}\gamma_5\psi_n^c(x) \quad (2.13)$$

and

$$\begin{aligned} e^{i\delta}\psi_{n,L}(x) &= -(\psi_n^c)_L(x) = -(\psi_{n,R})^c(x) \\ e^{i\delta}\psi_{n,R}(x) &= (\psi_n^c)_R(x) = (\psi_{n,L})^c(x), \end{aligned} \quad (2.14)$$

while the functions $\hat{f}_{n,L,R}(y)$ must satisfy the relation

$$\hat{f}_{n,L,R}(-y) = \hat{f}_{n,R,L}^*(y), \quad (2.15)$$

therefore leaving one independent function, as expected. In the second case, one has $\psi_n(x) = \gamma_5 \psi_n^c(x)$ and $\hat{f}_{n,L,R}(-y) = e^{-i\delta} \hat{f}_{n,R,L}^*(y)$. When instead ordinary boundary conditions are imposed, the Dirac nature of the 5D fermion fields is preserved and the two y -dependent functions $\hat{f}_{n,L,R}$ are subject to the constraints $\hat{f}_{n,L,R}(-y) = \mp \hat{f}_{n,L,R}(y)$, or viceversa.

In both cases, and after Kaluza-Klein decomposition, the periodic boundary conditions $\psi_{L,R}(x, \pi R) = \psi_{L,R}(x, -\pi R)$ lead to $\hat{f}_{n,L,R}(\pi R) = \hat{f}_{n,L,R}(-\pi R)$, implying that odd functions of the fifth coordinate will vanish at the boundaries $\pm \pi R^4$.

2.2 Boundary conditions in terms of Weyl spinors.

We can decompose the 5D Dirac spinor $\psi = \psi_L + \psi_R$ in terms of a L-handed and a R-handed Weyl spinor as follows

$$\psi_L = \begin{pmatrix} \phi \\ 0 \end{pmatrix} \quad \psi_R = \begin{pmatrix} 0 \\ \epsilon \xi^* \equiv \chi \end{pmatrix}, \quad (2.16)$$

where $\epsilon \equiv i\sigma_2$. Charge conjugation in 5D is realized by

$$C = \gamma_1 \gamma_3 = i\sigma_2 \otimes \mathbb{1} = \begin{pmatrix} \epsilon & 0 \\ 0 & \epsilon \end{pmatrix}. \quad (2.17)$$

Working in the Weyl basis with $\gamma^0 = \begin{pmatrix} 0 & \mathbb{1} \\ \mathbb{1} & 0 \end{pmatrix}$ and $\gamma_5 = \begin{pmatrix} -\mathbb{1} & 0 \\ 0 & \mathbb{1} \end{pmatrix}$ we obtain

$$\psi^c(x, y) = C\gamma^0\psi^* = \begin{pmatrix} \epsilon \chi^* \\ \epsilon \phi^* \end{pmatrix} \quad (2.18)$$

and the pseudo-Majorana boundary conditions thus imply (in the simplified case $\delta = 0$)

$$\begin{aligned} \phi(x, -y) &= -\epsilon \chi^*(x, y) \\ \chi(x, -y) &= \epsilon \phi^*(x, y). \end{aligned} \quad (2.19)$$

The boundary condition $\psi(x) = \gamma_5 \psi^c(x)$ on the 4D fields implies

$$\begin{aligned} \phi(x) &= -\epsilon \chi^*(x) \\ \chi(x) &= \epsilon \phi^*(x). \end{aligned} \quad (2.20)$$

The 4D spinor can hence be written in terms of one Weyl spinor

$$\psi(x) = \begin{pmatrix} \phi(x) \\ \epsilon \phi^*(x) \end{pmatrix} = \begin{pmatrix} -\epsilon \chi^*(x) \\ \chi(x) \end{pmatrix} \quad (2.21)$$

under the 5D pseudo-Majorana conditions.

⁴Notice that in the most general case a phase factor is allowed, so that $\psi_{L,R}(x, \pi R) = e^{i\alpha} \psi_{L,R}(x, -\pi R)$. Antiperiodic boundary conditions have been considered in ref. [13] in a supersymmetric scenario.

2.3 The action in four dimensions

We determine the spectrum of the KK modes, their masses and wave functions, by solving an eigenvalue problem which can be obtained once an ansatz for the 4D fermion action is imposed to the 5D action in eq. (2.1). The problem is: find the eigenfunctions $\hat{f}_{n,L,R}$ and the associated eigenvalues of a y -dependent differential operator, subject to the given boundary conditions. After rewriting the 5D action in terms of L- and R-handed fields

$$\begin{aligned} S &= \int d^4x \int dy \sqrt{-g} \bar{\psi}(x, y) (ie^\sigma \not{\partial} + 2\gamma_5 \sigma' - \gamma_5 \partial_5 - m) \psi(x, y) \\ &= \int d^4x \int dy \sqrt{-g} \{ \bar{\psi}_L(x, y) ie^\sigma \not{\partial} \psi_L(x, y) + \bar{\psi}_R(x, y) ie^\sigma \not{\partial} \psi_R(x, y) + \\ &\quad + \bar{\psi}_R(x, y)(-2\sigma' + \partial_5 - m)\psi_L(x, y) + \bar{\psi}_L(x, y)(2\sigma' - \partial_5 - m)\psi_R(x, y) \}, \end{aligned} \quad (2.22)$$

and performing the Kaluza-Klein decomposition according to eq. (2.10)

$$\begin{aligned} S &= \int d^4x \int dy \frac{1}{2\pi R} \sum_{n,m} \left\{ \bar{\psi}_{n,L}(x) i \not{\partial} \psi_{m,L}(x) \hat{f}_{n,L}^* e^\sigma \hat{f}_{m,L} + \bar{\psi}_{n,R}(x) i \not{\partial} \psi_{m,R}(x) \hat{f}_{n,R}^* e^\sigma \hat{f}_{m,R} + \right. \\ &\quad \left. + \bar{\psi}_{n,R}(x) \psi_{m,L}(x) \hat{f}_{n,R}^* (\partial_5 - m) \hat{f}_{m,L} + \bar{\psi}_{n,L}(x) \psi_{m,R}(x) \hat{f}_{n,L}^* (-\partial_5 - m) \hat{f}_{m,R} \right\} \end{aligned} \quad (2.23)$$

we require that the effective 4D action is given by

$$S_{4D} = \int d^4x \sum_n [\bar{\psi}_n i \not{\partial} \psi_n - \mathcal{L}(m_n)] , \quad (2.24)$$

with a Majorana mass term $\mathcal{L}(m_n)$. This is guaranteed by the presence of the pseudo-Majorana boundary conditions. The form of the 4D kinetic term in eq. (2.24) and the use of the pseudo-Majorana boundary conditions imply the following normalization and orthonormality condition on the y -dependent functions

$$\frac{1}{2\pi R} \int_{-\pi R}^{\pi R} dy e^\sigma \hat{f}_{n,L,R}^*(y) \hat{f}_{m,L,R}(y) = \frac{1}{2} \delta_{n,m} . \quad (2.25)$$

The most general 4D Majorana mass term involving one Majorana spinor can be conveniently expressed as a function of L- or R-handed fields and in terms of the 4D charge conjugate fields. This reads

$$\mathcal{L}(m_n) = m_n (\bar{\psi}_L^c \psi_L + \bar{\psi}_L \psi_L^c)_n \quad \text{or} \quad m_n (\bar{\psi}_R^c \psi_R + \bar{\psi}_R \psi_R^c)_n , \quad (2.26)$$

where we defined $\psi_{L,R}^c \equiv (\psi_{L,R})^c$ and the charge conjugate fields are now $\psi^c = C_4(\bar{\psi})^T$, where C_4 is the charge conjugation matrix in four dimensions.

2.4 Charge conjugation from five to four dimensions

Once the Clifford algebra is built for a given number of spacetime dimensions $d = t + s$, with t timelike and s spacelike dimensions, there always exists a charge conjugation matrix C , such that [16]

$$C^T = -\epsilon C \quad \Gamma_a^T = -\tilde{\eta} C \Gamma_a C^{-1} \quad (2.27)$$

for $\epsilon = \pm 1$ and $\tilde{\eta} = \pm 1$, and $\{\Gamma_a, \Gamma_b\} = 2\eta_{ab}$ defines the Clifford algebra in the given spacetime. A formal proof and further details can be found in [16, 17, 18]. The unitarity of the charge conjugation matrix $C^\dagger = C^{-1}$ is true in any representation, while the charge conjugation matrix not necessarily squares to $\mathbb{1}$.

What it is relevant to observe is that for odd dimensions only one of the two choices, $\tilde{\eta} = +1$ or $\tilde{\eta} = -1$, can be used [16]. While in $d = 4$ the two solutions $\epsilon = +1, \tilde{\eta} = +1$ and $\epsilon = +1, \tilde{\eta} = -1$ are allowed, in $d = 5$ only the solution $\epsilon = +1, \tilde{\eta} = -1$ can be realized.

An often used realization of the charge conjugation in $d = 4$ is $C = i\gamma^2\gamma^0$, which satisfies

$$\begin{aligned} C^\dagger &= C^T = C^{-1} = -C & C^2 &= -\mathbb{1} \\ C\gamma^\mu C^{-1} &= -(\gamma^\mu)^T. \end{aligned} \quad (2.28)$$

This choice gives the relation $\gamma_5 C_5 = -C_4$. In the most general case we can choose a charge conjugation matrix in four dimensions with a phase factor, such that $C_4 = \eta\gamma^2\gamma^0$, and $|\eta|^2 = 1$. The matrix C_4 satisfies the following relations

$$\begin{aligned} C^\dagger &= C^{-1} = (\eta^*)^2 C & C^2 &= \eta^2 \mathbb{1} \\ C^T &= -C \\ C\gamma^\mu C^{-1} &= -(\gamma^\mu)^T, \end{aligned} \quad (2.29)$$

and it is immediate to verify that $\gamma_5 C_5 = -i\eta^* C_4$. In the case in which the phase factor $e^{-i\delta}$ of eq. (2.5) is absorbed into the boundary conditions for the 4D fields, they will satisfy the following relation

$$\psi(x) = e^{-i\delta} \gamma_5 C_5 \bar{\psi}^T(x) = -i\eta^* e^{-i\delta} C_4 \bar{\psi}^T(x) = -i\eta^* e^{-i\delta} \psi^c(x), \quad (2.30)$$

implying the usual Majorana condition in four dimensions, generalized with a phase factor coming from the freedom in the choice of 5D boundary conditions and the freedom in the construction of the charge conjugation matrix in four dimensions. Eq. (2.30) leads to the identities

$$\begin{aligned} \bar{\psi}_R \psi_L &= -i\eta^* e^{-i\delta} \bar{\psi}_R \psi_R^c = i\eta e^{i\delta} \bar{\psi}_L^c \psi_L \\ \bar{\psi}_L \psi_R &= -i\eta^* e^{-i\delta} \bar{\psi}_L \psi_L^c = i\eta e^{i\delta} \bar{\psi}_R^c \psi_R, \end{aligned} \quad (2.31)$$

thus implying that the 5D action in eq. (2.23) generates a 4D Majorana mass term if subject to pseudo-Majorana boundary conditions. Equivalently, the phase factor $e^{-i\delta}$ can instead be absorbed into the boundary conditions for $\hat{f}_{L,R}(y)$.

2.5 Solutions to the eigenvalue problem

In order to obtain the 4D action in eq. (2.24) the y -dependent functions $\hat{f}_{n,L,R}$ must be solutions of the equations

$$\begin{aligned} (-\partial_5 + m)\hat{f}_{n,L}(y) &= -i\eta^* e^{-i\delta} m_n e^\sigma \hat{f}_{n,R}(y) \\ (\partial_5 + m)\hat{f}_{n,R}^*(y) &= -i\eta^* e^{-i\delta} m_n e^\sigma \hat{f}_{n,L}^*(y), \end{aligned} \quad (2.32)$$

on the interval $[-\pi R, \pi R]$, with real masses m, m_n and $\hat{f}_{n,L,R}$ complex functions, differently from the ordinary Dirac case. Notice that the Z_2 invariance of the 5D action implies that we can restrict all y -dependent integrations from 0 to πR and the behaviour of the solutions for negative y should be fully determined by their Z_2 transformation properties. The solutions must also satisfy the pseudo-Majorana boundary conditions $\hat{f}_{n,L,R}(-y) = \hat{f}_{n,R,L}^*(y)$ and periodic boundary conditions $\hat{f}_{n,L,R}(-\pi R) = \hat{f}_{n,L,R}^*(\pi R)$. As anticipated, we can equivalently choose to remove the phase factor $e^{-i\delta}$ from equations (2.32), while imposing the boundary conditions $\hat{f}_{n,L,R}(-y) = e^{-i\delta} \hat{f}_{n,R,L}^*(y)$. We choose to illustrate this second case, in which we also set $-i\eta^* = 1$, so that $\psi_n(x) = \psi_n^c(x)$ is satisfied. With these substitutions, equations (2.32) should then be solved separately for the real and imaginary parts, giving

$$\begin{aligned} (-\partial_5 + m) \text{Re} \hat{f}_{n,L}(y) &= m_n e^\sigma \text{Re} \hat{f}_{n,R}(y) \\ (\partial_5 + m) \text{Re} \hat{f}_{n,R}(y) &= m_n e^\sigma \text{Re} \hat{f}_{n,L}(y), \end{aligned} \quad (2.33)$$

and the equations for the imaginary parts are obtained by replacing $\text{Re} f_{L,R} \rightarrow \text{Im} f_{L,R}$. Notice that eqs. (2.33) together with periodic boundary conditions tell us that we should seek for solutions with definite and opposite Z_2 parity, i.e. $\text{Re} \hat{f}_{n,L}(y)$ even and $\text{Re} \hat{f}_{n,R}(y)$ odd or viceversa. This constrains the phase δ of the boundary conditions and the shape of the bulk mass parameter m .

For real $e^{-i\delta}$ the pseudo-Majorana conditions imply that $\text{Re} f_L$ and $\text{Re} f_R$ always carry the same parity (the same being true for the imaginary parts). This condition only allows for the zero mode solution of eqs. (2.33) to survive, thus $m_n = 0$, the mass term $m = 0$ and $\hat{f}_{0,L}(y) = \hat{f}_{0,R}(y) \sim \text{const.}$ For imaginary $e^{-i\delta}$ the entire Kaluza-Klein tower is allowed; the pseudo-Majorana boundary condition implies in this case that $\text{Re} \hat{f}_L$ and $\text{Im} \hat{f}_R$ have the same parity, and opposite to $\text{Re} \hat{f}_R$ and $\text{Im} \hat{f}_L$, a condition always compatible with eqs. (2.33).

We expect that the complete solutions $\hat{f}_{n,L,R}(y)$ will be plane waves - the solutions of the flat case [14] - deformed by the warped geometry. Some more subtleties arise from the comparison with the ordinary Dirac case as it is shown below.

The solutions

Solutions to eqs. (2.33) can conveniently be found by deriving a second order partial differential equation which decouples the L- and R-handed modes, in complete analogy with what has been done in refs. [12, 8]. The coupled equations (2.32) are equivalent to the following second order partial differential equation on the interval $[-\pi R, \pi R]$

$$(-e^\sigma \partial_5 e^{-\sigma} \partial_5 + M^2) \text{Re} \hat{f}_{n,L,R}(y) = m_n^2 e^{2\sigma} \text{Re} \hat{f}_{n,L,R}(y), \quad (2.34)$$

with the mass-like term M^2 given by

$$M^2 = \mp m \sigma' \pm m' + m^2, \quad (2.35)$$

where $\sigma' = k\epsilon(y)$ and the upper (lower) sign for the L (R) modes. The form of M^2 depends on the shape of the bulk mass parameter m . In the ordinary Dirac case [12, 8] the bulk

mass must be Z_2 odd, thus usually defined as $m = c\sigma'$ proportional to the derivative of the warp factor. In the pseudo-Majorana case the bulk mass is Z_2 even, and we can in general allow for a bulk and a boundary contribution. However, no further calculation is needed while noticing that for m even the mass-like term M^2 will carry mixed parity. Hence, for any choice of m even, a definite Z_2 -parity solution to (2.33) only exists for $m = 0$. This seems to be a genuine consequence of the warped AdS_5 geometry with the extra dimension compactified on a S^1/Z_2 orbifold. We expect that some of these constraints might be released for more general choices of the geometry of extra dimensions, for example in the flat case [14].

It is convenient to rewrite eq. (2.34) in terms of the new variable $x = e^\sigma m_n/k$, and maintain for a few steps more the explicit dependence upon the mass-like parameter M^2 . We obtain

$$x^2 \frac{\partial^2 f_n}{\partial x^2} + \frac{\sigma''}{k^2} x \frac{\partial f_n}{\partial x} - \left(\frac{M^2}{k^2} - |x|^2 \right) f_n(x) = 0. \quad (2.36)$$

The boundary terms, proportional to $\sigma'' = 2k(\delta(y) - \delta(y - \pi R))$, should be treated separately and depend on the form of M^2 . Thus we seek for the general solution of

$$x^2 \frac{\partial^2 f_n}{\partial x^2} - \left(\frac{\hat{M}^2}{k^2} - |x|^2 \right) f_n(x) = 0, \quad (2.37)$$

where the reduced mass-like term $\hat{M}^2$ is obtained by subtracting the boundary terms. As noticed in ref. [12] a further redefinition $f(x) = e^{\sigma/2} \tilde{f}(x)$ reduces equation (2.37) to a Bessel equation for $\tilde{f}_n(x)$

$$x^2 \frac{\partial^2 \tilde{f}_n}{\partial x^2} + x \frac{\partial \tilde{f}_n}{\partial x} - \left(\frac{\hat{M}^2}{k^2} + \frac{1}{4} - |x|^2 \right) \tilde{f}_n(x) = 0 \quad (2.38)$$

the most general solution of which is a linear combination of Bessel functions $J_\alpha(x)$ and $Y_\alpha(x)$ of order $\alpha = \sqrt{\hat{M}^2/k^2 + 1/4}$, for x real [12, 8]. The complete solutions $f_n(y)$ are thus given by

$$f_n(y) = \frac{e^{\sigma/2}}{N_n} \left[J_\alpha \left(\frac{m_n}{k} e^\sigma \right) + b_\alpha(m_n) Y_\alpha \left(\frac{m_n}{k} e^\sigma \right) \right], \quad (2.39)$$

with normalization factor

$$N_n^2 = \frac{2}{\pi R} \int_{-\pi R}^{\pi R} dy e^{2\sigma} \left(J_\alpha \left(\frac{m_n}{k} e^\sigma \right) + b_\alpha(m_n) Y_\alpha \left(\frac{m_n}{k} e^\sigma \right) \right)^2, \quad (2.40)$$

where the coefficients $b_\alpha(m_n)$ and the mass spectrum eigenvalues m_n are determined by the specific boundary conditions.

When $\hat{M}^2$ has mixed parity, we must solve eq. (2.38) separately on the two branches $y > 0$ and $y < 0$, thus obtaining Bessel functions of different order on the two branches for the same mode n . As already concluded before, the existence of a solution implies that $M^2 = 0$. The case $m = 0$, $M^2 = 0$ is immediately solved, the solutions being Bessel functions of order $\alpha = 1/2$. They are trigonometric functions $J_{1/2}(x) = \sqrt{2/\pi x} \sin x$

and $Y_{1/2} = -J_{-1/2}(x) = -\sqrt{2/\pi x} \cos x$. The coefficients $b_{1/2}(m_n)$ are determined by the boundary conditions at $y = 0, \pi R$ (the term proportional to σ'' in eq. (2.36))

$$\left. \frac{df_n}{dy} \right|_{y=0, \pi R} = 0 \quad (2.41)$$

for Z_2 even solutions and

$$f_n(y)|_{y=0, \pi R} = 0 \quad (2.42)$$

for Z_2 odd solutions. In this case $f_n(y) = \sigma'/k f_n(|y|)$ and the condition $f_n(0) = f_n(\pi R) = 0$ directly implies (2.41). We obtain the simple result

$$\begin{aligned} b_{1/2}(m_n) &= -\frac{\frac{1}{2}J_{1/2}(\frac{m_n}{k}) + \frac{m_n}{k}J'_{1/2}(\frac{m_n}{k})}{\frac{1}{2}Y_{1/2}(\frac{m_n}{k}) + \frac{m_n}{k}Y'_{1/2}(\frac{m_n}{k})} = -\cot\left(\frac{m_n}{k}\right) \\ b_{1/2}(m_n) &= b_{1/2}(m_n e^{\pi k R}) \end{aligned} \quad (2.43)$$

for the even solutions and

$$\begin{aligned} b_{1/2}(m_n) &= -\frac{J_{1/2}(\frac{m_n}{k})}{Y_{1/2}(\frac{m_n}{k})} = \tan\left(\frac{m_n}{k}\right) \\ b_{1/2}(m_n) &= b_{1/2}(m_n e^{\pi k R}) \end{aligned} \quad (2.44)$$

for the odd solutions respectively, with $n = 1, 2, \dots$. Thus the even parity solutions are

$$f_n(y) = \sqrt{\frac{k\pi R}{4(e^{k\pi R} - 1)}} \cos\left(\frac{m_n}{k}(e^\sigma - 1)\right) \quad (2.45)$$

and the odd parity solutions are

$$f_n(y) = \frac{\sigma'}{k} \sqrt{\frac{k\pi R}{4(e^{k\pi R} - 1)}} \sin\left(\frac{m_n}{k}(e^\sigma - 1)\right). \quad (2.46)$$

The same conditions, (2.43) or equivalently (2.44), give the exact spectrum of eigenvalues m_n :

$$m_n = n\pi k \frac{e^{-k\pi R}}{1 - e^{-k\pi R}}. \quad (2.47)$$

This can be compared with the Dirac case with ordinary boundary conditions, where one gets an estimate in the limit $kR \gg 1$ and $m_n \ll k$ given by [12] $m_n \approx (n + \alpha/2 - 3/4)\pi k e^{-k\pi R}$ for even solutions and $m_n \approx (n + \alpha/2 - 1/4)\pi k e^{-k\pi R}$ for odd solutions, and $\alpha = 1/2$ in our case.

Summarizing, the pseudo-Majorana boundary conditions imposed on fermions living on a slice of AdS_5 generate a Kaluza-Klein tower of Majorana spinors in the four dimensional action. No Dirac type bulk mass term seems to be allowed in this case by the warped geometry with orbifolding. The phase factor $e^{i\delta}$ in the pseudo-Majorana boundary conditions must be chosen along with the choice of the 4D charge conjugation matrix. We have derived the explicit solutions for pseudo-Majorana boundary conditions given by (imaginary phase) $\psi(x, -y) = \pm i\gamma_5 \psi^c(x, y)$, with $C_4 = i\gamma^0 \gamma^2$. This induces the Majorana condition

$\psi = \psi^c$ in four dimensions. A massless zero mode exists and all Kaluza-Klein modes, including the zero mode, are localized on the visible ($y = \pi R$) brane. In the same context, we have noticed that the opposite choice (real phase) $\psi(x, -y) = \pm \gamma_5 \psi^c(x, y)$ removes all excited states and only allows for a zero mode. For the moment we leave open the question of what mechanism might be in place that favours one choice and not the other.

The y -dependent wave functions of the Majorana Kaluza-Klein tower are deformed plane waves, as expected, and given by

$$\begin{aligned}\hat{f}_n(y) &= \sqrt{\frac{k\pi R}{4(e^{k\pi R} - 1)}} \left(\cos\left(\frac{m_n}{k}(e^\sigma - 1)\right) + i\frac{\sigma'}{k} \sin\left(\frac{m_n}{k}(e^\sigma - 1)\right) \right) \quad n = 1, 2 \dots \\ \hat{f}_0(y) &= \sqrt{\frac{k\pi R}{4(e^{k\pi R} - 1)}}.\end{aligned}\tag{2.48}$$

These results show that the case of bulk fermion fields with pseudo-Majorana boundary conditions is far more constrained than the ordinary Dirac case. A bulk Majorana mass term can still be added to our case, in analogy to what has been done in the ordinary case in ref. [9]. Again, the mass parameter will acquire opposite Z_2 parity with respect to the ordinary case if pseudo-Majorana boundary conditions are imposed. Notice finally that in the ordinary Dirac case the localization of the zero modes is monitored by the bulk Dirac mass, which accelerates or reduces the exponential decay of the zero mode y -dependent wave function. By tuning the bulk mass parameter one can achieve localization of the zero modes on the Planck brane, delocalization, or localization on the TeV brane. The pseudo-Majorana case produces a zero mode Majorana spinor which is localized on the TeV brane.

3. Neutrino phenomenology, Dirac or Majorana

The main purpose of this paper is the one of solving the exercise of generating Majorana spinors in four dimensions, starting from a five dimensional scenario with a warped geometry and bulk Dirac fermions. We did this by imposing non-standard pseudo-Majorana boundary conditions in 5D, instead of the ordinary boundary conditions which preserve the Dirac nature of bulk fermions. This exercise motivates the more phenomenological question of whether the found solution can at all give rise to a plausible mechanism to generate small masses for neutrinos. This is part of the many attempts in the literature at finding a convincing explanation of why the observed masses of fermions, quarks and leptons and in particular neutrinos, are the way they are, respecting a hierarchy among families and with neutrinos much lighter than all their Standard Model partners.

The pseudo-Majorana boundary conditions do not leave much space for tuning. With this mechanism we can generate a zero mode Majorana spinor which is localized on our brane, with or without a Kaluza-Klein tower of states. We can either identify the bulk fermion field with a “sterile” Majorana neutrino, i.e. a neutrino which is not charged under the SM gauge group, or with the Standard Model neutrino. In the first case a well known successful mechanism in four dimensions is the see-saw mechanism, where a sterile

R-handed heavy neutrino is added to the particle content of the Standard Model. We might identify the first Kaluza-Klein mode (or the tower of KK modes) of the Majorana spinor in the bulk with the “heavy” sterile neutrino and induce a see-saw mechanism, while all SM particles are localized on the TeV brane. The mass of the Kaluza-Klein modes is naturally of the TeV order, and might induce a too small suppression of the SM neutrino masses. However, a complete description of this mechanism can only be achieved with the full understanding of how Kaluza-Klein higher modes are entangled to the four dimensional effective theory. This might imply deviations from the assumptions implicit in the Kaluza-Klein decomposition.

A complete mass term in 4D might be of the type

$$S_M = \int d^4x \sum_{n \geq 1} m_n \bar{\psi}_R^{c(n)} \psi_R^{(n)} + \sum_{n \geq 0} Y_5 f_R^{(n)}(y = \pi R) \bar{L}(x) < \tilde{H} > \psi_R^{(n)}(x). \quad (3.1)$$

The usual see-saw mechanism in four dimensions predicts $m_{light} \sim v^2/M$ and $m_{heavy} \sim M$, with v the weak-scale vev of the neutral component of the Higgs doublet and M a GUT scale. In the 5D case here discussed, and considering the tower of Kaluza-Klein excitations we can generate Dirac masses in the four dimensional theory through Yukawa couplings proportional to $Y_5^{(n)} f_R^{(n)}(y = \pi R)v$ and Majorana masses m_n which are naturally of order the TeV. One needs to know the behaviour of $Y_5^{(n)} f_R^{(n)}(y = \pi R)$ for the excitations in the KK tower in order to predict a hierarchy of scales. In the simplest scenario in which all couplings and masses are of order the weak scale, no hierarchy will be generated. However, a suppression might be induced by the suppression of the couplings of KK excitations to the visible brane.

As a side note we add that in the case in which Majorana masses and Dirac masses are of the same order of magnitude and sufficiently small, the see-saw mass matrix would give rise to large mixing angles, inducing neutrino-antineutrino oscillations of the type $\nu_L \rightarrow (\nu_R)^c$. This would mean oscillations in which the SM neutrinos turn into “sterile” particles. This alternative idea has been explored long ago in [19, 20].

The depicted scenario can be compared with the Dirac case discussed in ref. [8], where the R-handed bulk fermion zero mode is identified with a sterile neutrino. In this case the bulk mass term can be used as a free parameter to tune the amount of localization of the zero mode. Above a critical value of the bulk mass ($c=1/2$) the Z_2 even (R-handed) zero mode is localized on the Planck brane, so that its wave function at the TeV brane is strongly suppressed. By introducing a “new Yukawa” interaction $Y_5 \bar{L}(x) \tilde{H}(x) \psi^{(0)}(x, y = \pi R)$, the four dimensional Yukawa coupling will be given by $Y_5 f_{0,R}(y = \pi R)$, with $Y_5 = O(1)$ and the SM neutrino mass induced via the Higgs mechanism $m_\nu \sim Y_5 v f_{0,R}(y = \pi R)$ receives an exponential suppression given by $f_{0,R}(y = \pi R)$ the value of the y -dependent function at the TeV brane. This beautiful mechanism however requires a fine-tuning of the bulk mass term. Nevertheless it has been shown [8] to be very effective in producing plausible ranges of neutrino masses and oscillation parameters.

The second possibility is to identify bulk fermion fields with SM particles. This implies that gauge fields should also be allowed in the bulk. We do not consider here this possibility, rather we observe that a scenario with all SM fields in the bulk offers many more

appealing features if supersymmetry is imposed. In the simplest case, and disregarding gauge interactions, the zero mode of the bulk Majorana field can be identified with the SM L-handed neutrino. Given its Majorana nature, no Yukawa coupling to the Higgs doublet and therefore Dirac mass term can be generated, while a mass term can be induced by the coupling with a Higgs triplet. The smallness of neutrino masses would in this case be explained by the smallness of the Higgs triplet vev, a well known mechanism in the four dimensional theory. The fitted value of the ρ parameter of the Standard Model restricts the ratio of the Higgs triplet to the doublet vevs to be approximately $v_T/v_H < 0.17$, thus naturally implying a suppression of neutrino masses with respect to charged SM fermions. In this scenario, the question of the smallness of neutrino masses is moved into the question of the smallness of a Higgs triplet vev and a hierarchy of fermion masses would be due to a hierarchy of scalar boson masses.

Alternatively, a mechanism in which higher order radiative corrections give rise to a small mass for the Majorana zero mode remains a viable solution.

4. Other mechanisms to generate small Majorana masses in a warped geometry

It is now part of textbooks the list of recipes to follow in order to generate a small neutrino mass in our four-dimensional world. Three possibilities are foreseen i) enlarging the SM lepton sector (e.g. with the addition of an $SU(2)$ singlet R-handed neutrino), ii) enlarging the SM Higgs sector (e.g. with the addition of a Higgs triplet and extra doublets) and iii) enlarging both. Fermions in the bulk of (compactified) extra dimensions offer an additional mechanism of enhancement or suppression of interactions and generation of mass terms.

However, no clear mechanism has been isolated that can explain why neutrino masses are much smaller than charged lepton masses, and most of the proposed mechanisms do rely on a fine tuning procedure. Experimentally, no evidence in favour or against the Majorana nature of neutrinos has been reported, apart from a long debated claim of the Gran Sasso neutrinoless double β -decay experiment. For an up to date analysis of neutrino data see e.g. [21]. Results collected along the years seem to indicate that some relevant ingredient is missing, perhaps a fundamental symmetry principle, a group theory consideration [22, 23] that might explain the recurrence of the three-family structure in the fermion spectrum of the standard model without the need for a fine tuning. Might a random process have a role in explaining the observed hierarchies? It should possibly occur jointly with an enhancement mechanism acting on an initial tiny symmetry breaking effect. An intriguing use of randomness has been made in ref. [24] in order to describe the apparent hierarchy of atmospheric and solar neutrino oscillation parameters.

In the context of warped extra dimensions, the main attempts to generate a small Majorana mass for neutrinos on the visible brane, can be summarized as follows: i) Higher dimensional operators such as the operator $\psi^T C H^2 \psi$ [10] can induce a Majorana mass term on the visible brane. The suppression of the neutrino mass w.r.t. the charged lepton mass is obtained when the 5D wave function of the zero mode is localized on the Planck brane, similarly to what originally proposed in ref. [8]. ii) The addition of a bulk Majorana mass on

the Planck brane [9] in the case of bulk fermion fields with ordinary boundary conditions can induce an uplifting of the mass of the bulk fermion zero mode, which can thus be identified with the R-handed heavy neutrino of a see-saw mechanism. iii) Finally the role of additional scalar fields in the bulk has been explored in ref. [11]. Assuming a L-handed neutrino on the visible brane, we can generate a Majorana mass term via the interaction with an $SU(2)$ Higgs triplet: $\lambda_{ij} L_i^T C^{-1} (i\tau_2 T) L_j$, with obvious notation. The vev of the neutral component, call it ξ_0 , of the Higgs triplet T will thus induce a Majorana mass term $\sim \lambda_{ii} \xi_0$. Therefore, a suppression of the triplet vev w.r.t. the doublet vev would account for a suppression of the Majorana neutrino mass w.r.t. the charged fermion masses. It was concluded in ref. [11] that the introduction of bulk scalar fields would suffice to guarantee a suppressed triplet vev on the visible brane, thus offering a viable mechanism for the generation of a suppressed Majorana mass for SM neutrinos. However, after reconsidering the proposed model, we find [25] that no suppression mechanism can actually be obtained⁵. We briefly summarize the most relevant steps of the derivation and provide some physics considerations. The model contains one bulk scalar singlet field $S(x, y)$, a Higgs triplet $T(x)$ and a Higgs doublet $H(x)$ on the visible brane. Denoting with ξ_0 and v the vevs of the neutral triplet and doublet respectively, the desired hierarchy of vevs should be $\xi_0 \ll v$, while the vev of the bulk scalar singlet, call it S_0 , should induce such hierarchy.

The action for a bulk scalar field has also been derived in ref. [12], where the 5D equations of motion for bulk scalar, vector and fermion fields are represented in a useful compact form. Through power counting, we can write the most general potential for the singlet field and its interactions with the triplet and doublet on the brane, up to and including quartic couplings. The potential we find does agree with that of ref. [11]. The bulk singlet field with a generic mass term $ak^2 + b\sigma''$ – a bulk and a boundary contributions are allowed by Z_2 invariance – has a zero mode if $b = 2 - \alpha$, with $\alpha = \sqrt{4 + a}$. This relation between the bulk and boundary terms can be justified in the supersymmetric limit [12]. As a consequence, the localization of the singlet zero mode is driven by the parameter α : it will be localized on the Planck brane for $\alpha > 1$, on the TeV brane for $\alpha < 1$ and delocalized for $\alpha = 1$. The author of ref. [11] points out that the Planck localized case can provide the required hierarchy. However, we find a different rescaling of the coupling of the quartic self-interaction of the singlet field λ_S when reducing from five to four dimensions, with crucial consequences for the physics conclusion. The coupling λ_S rescales as follows

$$\tilde{\lambda}_S = \frac{\lambda_S}{M_P^2} \frac{1}{4\pi^2 R^2} \frac{1}{N_0^4} e^{4(1-\alpha)k\pi R} \quad (4.1)$$

where

$$N_0^{-1} = \sqrt{\frac{2(1-\alpha)k\pi R}{e^{2(1-\alpha)k\pi R} - 1}} \quad (4.2)$$

and, for $\alpha > 1$, $kR \gg 1$

$$N_0^2(\alpha > 1, kR \gg 1) \simeq \frac{1}{2(\alpha - 1)k\pi R}. \quad (4.3)$$

⁵A rescaling of a quartic interaction in going from the 5D to the 4D action of the singlet scalar field seems to be missing in ref. [11]

For $\alpha > 1$ all couplings of the 5D potential rescale as follows

$$\begin{aligned}
\tilde{\lambda}_H &= \lambda_H & \tilde{\lambda}_T &= \lambda_T & \tilde{\lambda}_S &= \frac{\lambda_S}{M_P^2} k^2 (\alpha - 1)^2 e^{-4(\alpha-1)k\pi R} \\
\tilde{\eta} &= \eta & \tilde{\xi} &= \xi \sqrt{\alpha - 1} \sqrt{\frac{k}{M_P}} e^{-(\alpha-1)k\pi R} \\
\tilde{\chi}_i &= \chi_i (\alpha - 1) \frac{k}{M_P} e^{-2(\alpha-1)k\pi R} \quad i = 1, 2 & \tilde{\mu}_{H,T}^2 &= \mu_{H,T}^2 k^2 e^{-2k\pi R},
\end{aligned} \tag{4.4}$$

where the first line contains all quartic self-interactions, and the remaining two lines contain the couplings of the allowed mixed interactions of singlet, triplet and doublet, $\eta, \xi, \chi_{1,2}$ and the doublet and triplet masses $\mu_{H,T}$. For $k \simeq M_P$ the warped geometry is providing a suppression of the couplings. Denoting with A the suppression factor

$$\begin{aligned}
A &= \sqrt{2(\alpha - 1)} \sqrt{\frac{k}{M_P}} e^{(1-\alpha)k\pi R} & \alpha > 1 \\
A &= \sqrt{2(1 - \alpha)} \sqrt{\frac{k}{M_P}} & \alpha < 1 \\
A &= \frac{1}{\sqrt{kR}M_P} & \alpha = 1,
\end{aligned} \tag{4.5}$$

we obtain $\tilde{\lambda}_S = A^4 \lambda_S$, $\tilde{\chi}_{1,2} = A^2 \chi_{1,2}$ and $\tilde{\xi} = A \xi$, thus providing the hierarchy of couplings $\tilde{\lambda}_S \ll \tilde{\chi}_{1,2} \ll \tilde{\xi}$. Once the hierarchy of couplings is obtained, the solutions of the equations which minimize the complete potential will provide the hierarchy of the associated vevs. The set of coupled equations

$$\begin{aligned}
2\tilde{\lambda}_H v^3 + v(\tilde{\mu}_H^2 + \tilde{\eta}\xi_0^2 + \tilde{\xi}S_0\xi_0 + \tilde{\chi}_2 S_0^2) &= 0 \\
4\tilde{\lambda}_T \xi_0^3 + 2\xi_0(\tilde{\mu}_T^2 + \tilde{\eta}v^2 + \tilde{\chi}_1 S_0^2) + \tilde{\xi}S_0 v^2 &= 0 \\
4\tilde{\lambda}_S S_0^3 + 2S_0(\tilde{\chi}_1 \xi_0^2 + \tilde{\chi}_2 v^2) + \tilde{\xi}\xi_0 v^2 &= 0
\end{aligned} \tag{4.6}$$

can be easily analyzed without the need for an exact solution. From the third equation, by assuming $\xi_0 \ll v$ we get $\xi_0 \ll AS_0$ and $S_0 \sim v/A$, thus enhanced! The second equation, using $S_0 \sim v/A$, implies that $\xi_0 \sim v$ is the only allowed non trivial solution. Therefore, the produced hierarchy is $S_0 \sim v e^{(\alpha-1)k\pi R} \gg v$ and $\xi_0 \sim v$. This conclusion is completely in agreement with the fact that once the singlet field is localized on the Planck brane, it has to acquire a vev of order the Planck scale. Unfortunately, this also means that no mechanism is left to provide a suppressed triplet vev on the visible brane via the addition of a singlet bulk scalar field with self-interacting potential. The cases of a delocalized and TeV-localized singlet field are also not relevant to our purpose. For $\alpha = 1$, a power-like enhancement of the singlet field $S_0 \sim \sqrt{kR}v$ is generated, while again $\xi_0 \sim v$. For $\alpha < 1$ no hierarchy is produced, with $S_0 \sim \xi_0 \sim v$.

5. Conclusions

In the context of warped extra dimensions, we have explored the possibility of imposing boundary conditions on the bulk fermion fields which mix fields and their charge conjugate

under a Z_2 parity transformation involving the warped extra dimension. We have called these unordinary boundary conditions *pseudo-Majorana* conditions, since they induce the usual Majorana constraint on spinors in four dimensions. They can be written as

$$\psi(x, -y) = e^{-i\delta} \gamma_5 \psi^c(x, y), \quad (5.1)$$

where a phase factor is allowed in the most general case. This is a particular case of a general analysis proposed in [14] in the case of universal flat extra dimensions. The warped geometry with orbifolding induces peculiar behaviours of the allowed spectrum of fermion fields obtained in the reduction from five to four dimensions via the usual Kaluza Klein decomposition.

In particular, we have shown that the pseudo-Majorana boundary conditions generate a Kaluza-Klein tower of Majorana spinors in the four dimensional action. No Dirac type bulk mass term seems to be allowed by these boundary conditions embedded in the warped geometry with orbifolding. The phase factor $e^{i\delta}$ in the pseudo-Majorana boundary conditions must be chosen along with the choice of the phase in the 4D charge conjugation matrix. A massless zero mode exists and all Kaluza-Klein modes, including the zero mode, are localized on the visible ($y = \pi R$) brane. We have also noticed that a particular choice of the phase factor $e^{i\delta}$ forbids all excited states and only allows for a zero mode solution. The y -dependent wave functions of the Majorana Kaluza-Klein tower are plane waves deformed by the warped geometry.

These results show that the case of bulk fermion fields with pseudo-Majorana boundary conditions is far more constrained than the ordinary Dirac case. No tuning of a localization mechanism via the bulk mass term is allowed in the Majorana case. It remains interesting the possibility to generalize these boundary conditions allowing for a superposition of ψ and ψ^c after a Z_2 transformation. There is also the option of adding a bulk Majorana mass term, analogously to ref. [9]. But again, the mass parameter will acquire opposite Z_2 parity with respect to the ordinary case if pseudo-Majorana boundary conditions are imposed. Bulk Majorana spinors can be naturally identified with sterile neutrinos with masses of order the weak scale or with a massless Majorana Standard Model neutrino.

Finally, after reconsidering a derivation proposed in [11], we have shown that an additional bulk singlet scalar field cannot induce a suppression of a Higgs triplet vev w.r.t. a Higgs doublet vev both confined on the visible brane. Unfortunately, our conclusion seems to rule out the possibility that a singlet bulk scalar field could induce a small mass for a Standard Model Majorana neutrino via the Yukawa interaction with a Higgs triplet. Although we suspect that this result extends to more general choices of scalar fields and their interactions, an interesting task is still the one of generating small Majorana masses through a hierarchy of scalar vevs, possibly induced by the geometry of extra dimensions.

5.1 Acknowledgments

We acknowledge interesting discussions with Eric Bergshoeff, Mees de Roo, Avihay Kadosh, Jos Postma, Duurt Johan van der Hoek, and correspondence with M-C. Chen.
